

(Discussion 1) To begin with, after we wrote some queries for question one, we learned that even though we omit null values in the cleaning phase, we got a lot of zeros in our result. This finding affected our question one since the majority of the games include value zero in the playtime table. We thought the reason is that the game might not be released yet or it is a new game. Therefore, we would only include the games that had non-zero average playtime.

(Discussion 2) For our second question, after doing the queries for the condition one of our most popular definitions, we realized that because of using integer division, most of our data is missing in our tables. The reason is that when using division on numerator that is an integer, there will be some values missing due to rounding at the end. Thus, we decide to cast our numerator's column into float numbers, then using division with float numbers to avoid missing rows.
